

### C1

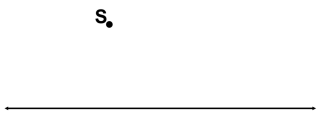

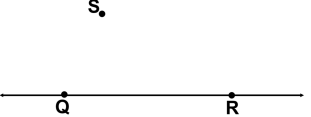

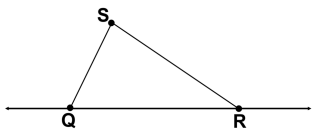

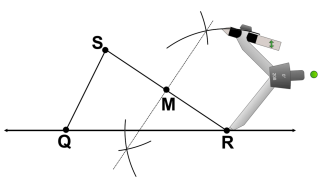

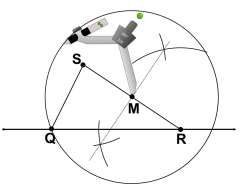

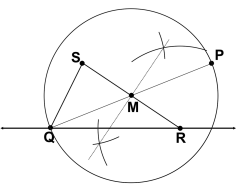

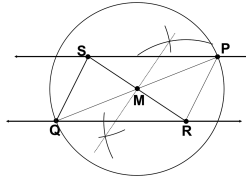

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Start with a segment length for the sides of the triangle.</p>	<p>Gives us a length to use for the sides of the triangle</p>
	<p>2. Construct circle A with the given radius.</p>	<p>Shows all the points a fixed distance from point A</p>
	<p>3. Choose point B on circle A and connect A and B to make the first side of equilateral triangle ABC.</p>	<p>Starts the triangle with side AB</p>
	<p>4. Construct circle B with the same radius as circle A.</p>	<p>Shows all the points a fixed distance from point B</p>
	<p>5. Label point C where circles A and B intersect.</p>	<p>The third vertex (point) of the equilateral triangle because C is on both circles A and B.  <math>AB = AC = BC</math> because circles A and B are constructed with the same radius, and AC, BC, and AB are all radii of circle A and/or circle B</p>
	<p>6. Connect A to C and B to C to complete the second and third sides of equilateral triangle ABC.</p>	<p>The other two sides of the triangle</p>

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Use the same radius for all circles in this construction. Start with circle <i>H</i>. All vertices of the hexagon will be on circle <i>H</i>.</p>	<p>All points that are a fixed distance from point <i>H</i>.</p>
	<p>2. Choose a point on circle <i>H</i> and label it <i>E</i>.</p>	<p>The first vertex (corner) of the hexagon.</p>
	<p>3. Construct circle <i>E</i> (same radius as circle <i>H</i>). Label points <i>X</i> and <i>N</i> where circles <i>H</i> and <i>E</i> intersect.</p>	<p>Two more vertices (corners) of the hexagon both the distance <i>EH</i> from points <i>E</i> and <i>H</i></p>
	<p>4. Construct circle <i>X</i> and label point <i>A</i> where circles <i>H</i> and <i>X</i> intersect.</p>	<p>One more vertex (corner) of the hexagon which is the distance <i>EH</i> from points <i>X</i> and <i>H</i></p>
	<p>5. Construct circle <i>A</i> and label point <i>G</i> where circles <i>H</i> and <i>A</i> intersect.</p>	<p>One more vertex (corner) of the hexagon which is the distance <i>EH</i> from points <i>A</i> and <i>H</i></p>
	<p>6. Construct circle <i>G</i> and label point <i>O</i> where circles <i>H</i> and <i>G</i> intersect.</p>	<p>One more vertex (corner) of the hexagon which is the distance <i>EH</i> from points <i>G</i> and <i>H</i></p>
	<p>7. Connect points <i>E</i>, <i>X</i>, <i>A</i>, <i>G</i>, <i>O</i>, and <i>N</i> to complete the regular hexagon.</p>	<p>The sides of the hexagon all equal based on the work in steps 1 through 6 – a series of circles with the same radius</p>

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Start with <math>\angle ABC</math>.</p>	<p>Gives us angle to bisect</p>
	<p>2. Construct circle <math>B</math> that intersects both sides of <math>\angle ABC</math>.</p>	<p>Shows all the points a fixed distance from vertex <math>B</math></p>
	<p>3. Label points <math>D</math> and <math>E</math> where circle <math>B</math> intersects the sides of <math>\angle ABC</math></p>	<p>Gives us <math>BE = BD</math> because they are both radii of circle <math>B</math></p>
	<p>4. Construct circle <math>D</math> with any radius.</p>	<p>Gives us all points a fixed distance from <math>D</math></p>
	<p>5. Construct circle <math>E</math> with the same radius you used to construct circle <math>D</math>.</p>	<p>Gives us all points a fixed distance from <math>E</math> so that the points of intersection of circle <math>E</math> and circle <math>D</math> are equal.</p>
	<p>6. Mark the intersection of circle <math>D</math> and circle <math>E</math> that is inside <math>\angle ABC</math>. Label the intersection point <math>F</math>.</p>	<p>Gives us <math>F</math>, a point equidistant from the sides of angle <math>ABC</math> because <math>F</math> is equidistant from points <math>D</math> and <math>E</math></p>
	<p>7. Draw <math>\overrightarrow{BF}</math> which is the bisector of <math>\angle ABC</math></p>	<p>Ray <math>BF</math> shows the set of points equidistant from the sides of angle <math>ABC</math> (<math>BA</math> and <math>BC</math>) which means <math>BF</math> bisects the angle</p>

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Start with <math>\overline{AB}</math>.</p>	<p>Gives me a segment to bisect.</p>
	<p>2. Construct circle A with a radius that is greater than half the length of <math>\overline{AB}</math>.</p>	<p>Gives me all points a fixed distance from point A.</p>
	<p>3. Construct circle B with the same radius as circle A.</p>	<p>Gives me all points a fixed distance from point B.</p>
	<p>4. Label points C and D where circles A and B intersect.</p>	<p>Gives me two points, C and D that are equidistant from points A and B.</p>
	<p>5. Construct <math>\overleftrightarrow{CD}</math>, the perpendicular bisector of <math>\overline{AB}</math> and label the point where <math>\overleftrightarrow{CD}</math> and <math>\overline{AB}</math> intersect with an M.</p>	<p>Gives all points equidistant from points A and B, so the intersection of CD and AB, point M, must be equidistant from points A and B making it the bisector of AB. Since the <math>180^\circ</math> angle AMB is also bisected, AMC must be <math>90^\circ</math> resulting in perpendicular lines.</p>

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Start with <math>\angle ABC</math>.</p>	<p>An angle to copy</p>
	<p>2. From a new endpoint <math>B'</math>, draw a ray. This will become one side of the new angle.</p>	<p>Gives us one side of the new angle. Any ray will do because length of the side of an angle does not matter when we copy an angle</p>
	<p>3. Place the compass pivot point on <math>B</math>. Set the radius to a length so that an arc will intersect both sides. Draw an arc across both sides of the angle, creating the points <math>J</math> and <math>K</math> as shown.</p>	<p>Marks 2 points (<math>J</math> and <math>K</math>), one on each side of the angle, that are equidistant from the vertex <math>B</math>. This means that <math>\overline{JK} \cong \overline{J'K'}</math></p>
	<p>4. Without changing the radius, place the compass pivot point on <math>B'</math> and draw an arc, creating point <math>J'</math> as shown.</p>	<p>Marks <math>J'</math> on the first side of the angle such that the distance between <math>J'</math> and <math>B'</math> is the same as the distance between <math>J</math> and <math>B</math>. It also shows all possible locations for <math>K'</math> with respect to the vertex <math>B'</math></p>
	<p>5. Set the compass on <math>J</math> and adjust the radius length so the pencil is on point <math>K</math>.</p>	<p>Measures the distance between <math>K</math> and <math>J</math></p>
	<p>6. Without changing the compass radius, move the compass pivot point to <math>J'</math> and draw a new arc across the first arc, creating point <math>L</math> where they cross.</p>	<p>Marks locations that are the distance <math>JK</math> away from point <math>J'</math></p>
	<p>7. Draw a ray from <math>B'</math> through <math>K'</math>.</p>	<p>The intersection of the arcs shows the location for <math>K'</math> so that <math>\overline{BK} \cong \overline{B'K'}</math> and <math>\overline{BJ} \cong \overline{B'J'}</math> since we already have <math>\overline{JK} \cong \overline{J'K'}</math>, we get us 2 identical triangles and therefore identical angles <math>B</math> and <math>B'</math></p>

DIAGRAMS	STEPS	WHAT THIS DOES (justification)
	<p>1. Start with any line and a point not on the line.</p>	<p>A line and a point through which to construct a line parallel to the first line</p>
	<p>2. Mark and label any two points on the line</p>	<p>Two points on the line to be vertices of a triangle.</p>
	<p>3. Connect the three points to make a triangle. (triangle QRS in this example)</p>	<p>A triangle to rotate 180°.</p>
	<p>4. Construct the perpendicular bisector of one of the two sides that are not on the original line, in this example, <math>\overline{SR}</math> and mark point M</p>	<p>A midpoint to rotate the triangle around so that alternate interior angles will be congruent.</p>
	<p>5. Set the compass on point M with radius <math>\overline{MQ}</math> and construct circle M.</p>	<p>All possible points for P, the image of Q, when Q is rotated.</p>
	<p>6. Draw the diameter of circle M from point Q and label the other endpoint of the diameter P so that you have diameter <math>\overline{QP}</math>.</p>	<p>P at the other end of the diameter is a 180° rotation about point M of point Q so when connected with S and R, alternate interior angles will be congruent (rotation preserves angle measure).</p>
	<p>7. Draw <math>\overleftrightarrow{SP}</math>. This line is parallel to the original line <math>\overline{QR}</math></p>	<p>A line parallel to QR because the triangle has been rotated making alternate interior angles congruent</p>
